networkedsystemrepairkit.ps1

This commandlet works on windows systems (especially on windows systems that sleep/hibernate) in active directory environments. When executed in powershell it will run "powercfg hibernate off, netsh winsock reset, netsh int ip reset and gpupdate /force" commands in order and restart the system automatically when finished with gpupdate /force command.

These 4 commands on a laptop system will together clear the hibernation file (sometimes a suspect of various random power/wake up issues), reset the Winsock catalog (which can help resolve network connectivity issues), reset the TCP/IP stack to its default configuration (This can be helpful in resolving various network connectivity issues that aren't resolved by resetting the winsock catalog. "The command effectively removes custom TCP/IP configurations, such as static IP addresses or DNS settings, and reverts them to the defaults obtained through DHCP"). forces an update of Group Policy settings on a Windows computer. gpupdate /force "re-applies all Group Policy settings, regardless of whether they have been changed, ensuring the computer's settings are synchronized with the domain's policy." The force switch will also when completed re-applying group policy settings restart the computer.

Disclaimer: When using any command that requires system reset or applications to close ensure the End user (EU / client / customer) has their work already saved to the latest version of the project.

What they each do by themselves.

Key Differences:

1. **Powercfg hibernate off** will prevent the system from entering hibernation mode and also remove the [hiberfil.sys](#) file, potentially freeing up disk space as well as some basic troubleshooting of wake/sleep issues when the hiberfil.sys file becomes corrupted. While this can be manually turned back on upon restart of the system, Windows enterprise laptops reinstall the hiberfill.sys file like new.
2. **netsh** is a command-line scripting utility in Windows used for configuring and monitoring network devices and connections. Specifically used here are the sub-commands:
 - a. **winsock reset** puts the TCP/IP stack to its default configuration
 - b. **int ip reset** to resolve network connectivity issues.
3. **gpupdate** vs. **gpupdate /force**:
The basic **gpupdate** command only applies new or changed Group Policy settings.
gpupdate /force applies all settings, including those that haven't changed.

When to use `gpupdate /force`:

Use `gpupdate /force` when you want to be certain that all Group Policy settings are up-to-date, or when troubleshooting policy-related issues.

Invoke-GPUUpdate:

In PowerShell, the `Invoke-GPUUpdate` cmdlet performs a similar function and can be used to force updates on remote computers
